The operational assessment included a total of 12 missions in 2 designated UUV operating areas that contained moored and bottom mine targets accredited by the Navy Operational Test and Evaluation Force as foreign mine surrogates.

Navy operators trained in Knifefish operations and maintenance completed six missions in each UUV operating area to test Knifefish capability to detect, classify, and identify mines in two different operational environments.

To assess Knifefish capability to conduct simultaneous UUV missions without mutual interference, missions 6 and 12 launched an additional UUV, which operated in areas or vessels of opportunity, which are ships capable of launching the UUV and supporting Knifefish operations.

The MCM Commander (MCMC) will employ units equipped with Knifefish to conduct mine reconnaissance operations, such as area or route surveys, in littoral regions throughout the world in support of Combatant Commander operations.

without mine targets adjacent to the 2 designated UUV operating areas.

Assessment
- The testing was adequate within the scope of the test objectives; however, the testing occurred in areas and environments similar to those in which the system developers trained and tuned Knifefish’s PMA classification algorithm. Therefore, DOT&E is unable to assess how well the system will perform in operational environments that are new to the system.
- The test targets included a limited number of mine variants that were also used for system development. Testing did not provide data on the system’s capability to detect other mine variants or its capability to distinguish mines from non-mine, mine-like bottom objects, and clutter.
- Due to test limitations, DOT&E is unable to fully assess the system’s ability to detect, classify, and identify buried mines as a function of burial depth.
- While exceeding the operational availability threshold, the system did not meet the Navy’s reliability threshold due to operational mission failures. During two sorties, UUV hardware failures terminated the sorties. During PMA, hardware and software faults delayed completion of sensor data analysis.
- The operational assessment did not include an evaluation of cybersecurity since the system, software, and interfaces are still in development.
- A complete DOT&E analysis of Knifefish operational assessment test results is available in the classified SMCM UUV Knifefish OT-B1 report.
- Based on the operational assessment, the Navy plans to incrementally upgrade and test Knifefish capability to meet operational needs prior to IOT&E and fleet introduction.

Recommendations
The Navy should implement the following recommendations to improve operational performance prior to IOT&E and subsequent fleet introduction:

1. Complete system upgrades and conduct additional testing to more fully characterize Knifefish performance in operational environments in which the system capability has not previously been assessed.
2. Specific recommendations are available in the classified SMCM UUV Knifefish OT-B1 report.
